structures. Not all homologous structures have important functions. Vestigial structures are inherited from ancestors but have lost much or all of their original function due to different selection pressures acting on the descendant. For example, the hipbones of the bottlenose dolphin, shown on page 467, are vestigial structures.

Vestigial organs have long been one of the classic arguments used as evidence for evolution. The argument goes like this: living organisms, including man, contain organs that were once functional in our evolutionary past, but that are now useless or have reduced function. This is considered by many to be compelling evidence for evolution.

Two good examples are the vestigial legs in whales and some snakes. This is clear evidence that whales and snakes are descended from creatures that had functional legs. This is strong evidence of evolution, since there is no other plausible explanation, religious or scientific, for vestigial structures.

How do vestigial structures provide evidence of evolution

...

Vestiges are structures, anatomical configurations, and reflexes that are most parsimoniously explained as remnants of common ancestors in the evolutionary history of a given organism. As such, they are one of many sources of evidence for the model common ancestry, on which the evolutionary model is based.

Do vestigial structures provide evidence for degenerative evolution only? Huse actually says something along the above lines as well: Even if the concept of vestigial organs were valid, it still would not lend support to evolution since it implies structures on the way out, not in. Nascent organs, those under construction into a functional unit ...

Vestigial Structures | What are Vestigial Structures?

Why do scientists consider vestigial structures evidence for evolution? A vestigial structure is an example of a homologous structure that has apparently been reduced through evolution to a non-functional state because its function is no longer utilized by the species exhibiting it; therefore, any mutations which might reduce its structure are not selected against.

Evidence for common descent comes from the existence of vestigial structures. These rudimentary structures are often homologous to structures that correspond in related or ancestral species. A wide range of structures exist such as mutated and non-functioning genes, parts of a flower, muscles, organs, and even behaviors.
